

Chapter 14—Gene Linkage and Linkage Maps

1. Cross the F₁ self-fertilizing pea that is heterozygous for round seeds (allele R) and r) and heterozygous for Green seeds (allele G and g). Assume that these genes are on separate chromosomes that means they will independently sort.
2. Draw all of the possible gametes from this parent.
3. Cross the F₁ self-fertilizing pea that is heterozygous for wrinkled seeds (allele W and w) and heterozygous for yellow seeds (allele Y and y).
4. Draw all of the possible gametes from this parent.
5. determine distribution between the gametes in P₁ and the gametes in P₂. Draw the resulting cells. Indicate the phenotype.
6. Carry this cell through analysis drawing (A.A.) possible arrangements of chromosomes. Assume that no crossing-over occurs.

The number of genes in a cell for autosomes (the number of chromosomes in a cell). Therefore, every time one gene (usually hundreds or thousands of genes) are located on the same chromosome. How is inheritance of genes that are located on the same chromosome different from inheritance of genes that are located on separate chromosomes?

LINKAGE GROUPS—Genes located on the same chromosome that tend to be inherited together as genetic units because the chromosome is passing on as a unit. In other words, they DO NOT independently sort.

Morgan found that fruit flies usually had a gray body (wild type, R) and normal sized wings (wild type, vg⁺). However, he found mutant strains of each of the traits—black bodies (b) and vestigial wings (vg).

He started true-breeding wild-type flies with black, vestigial wings and produced the F₁ offspring.

7. Write the genotype of the wild-type P₁, the mutant P₁, and the F₁ offspring. What is the phenotype of the F₁ offspring?
8. He then crossed a dihybrid F₁ offspring with a double mutant. Write the genotype of these two flies and predict the phenotypic outcome of the F₂ generation based on Mendel's laws of segregation & independent assortment.
9. In Morgan's actual experiment, the proportion of F₂'s were 86% wild-type, 14% black-vestigial, 10% gray-vestigial, and 1% black-normal. What phenotype seemed to occur more often than Mendel's rules would suggest?

PHENOTYPIC REPEL—A phenotype that matches one of the parents.

RECOMBINANTS—Offspring that have new combinations of phenotypes different from either parent.

Morgan explained this phenomenon by suggesting that the genes for body color and wing size tend to be located on the same chromosome and that these genes were inherited together and DID NOT independently assort during meiosis.

10. Show the process of meiosis in the two parents described in 9. Draw a single pair of chromosomes that has BOTH the genes for body color and wing size. What types of gametes are possible for each of the parents? If random assortment occurs, what possible phenotypes (PHENOTYPIC REPEL) are in the offspring?
11. How does Morgan's actual data (in 9) differ from your predicted outcome in the previous above.
12. What phenomenon could account for the appearance of recombinants from a cross that involved linked genes?

If a 50% frequency of recombinants is noted (a total of 50% recombinants) is observed for any two genes they are determined to be on different chromosomes. If there is a frequency less than 50%, the genes are determined to be linked (on the same chromosome). The higher the frequency (from 0% to 50%) the more often crossing over occurs.
