

CHAPTER 3, PROBLEM 9

- I. We expect B_1 to be less than 0 since we can expect a negative correlation between the two variables. The increase in nitrous oxide levels can make the houses in a certain area attractive. For B_2 , we expect to see a positive correlation since we can assume that more rooms will equal a bigger house, *ceteris paribus*. The only unknown is that we do not know the size of each room which can cause uncertainty in our data, which would increase our error term (μ).
- II. The correlation between x_1 and x_2 is less than 0 whilst $B^2 > 0$, so our simple linear regression estimator will be \widehat{B}^1 which we can assume that there will be a downward bias in our model. Also, if we look at B^1 which will be less than 0, we can conclude that $\log(\text{price})$ will be overpowering, resulting in a negative trend.
- III. We can see that we have two estimated equations, one that includes B^2 and one that does not take B^2 into account,
 - (1) $\log(\text{price}) = 11.71 - 1.043 \log(\text{nox}), n = 506, R^2 = 0.264$
 - (2) $\log(\text{price}) = 9.24 - 0.718 \log(\text{nox}) + 0.306 \text{rooms}, n = 506, R^2 = 0.514.$

A big difference between the two estimated equations is the R^2 . We can see that in the second equation, where we include rooms, the two variables explain more of the data contrary to the first equation. We also notice that our B^1 gets more significant on $\log(\text{price})$ in the second equation because its coefficient has a more significant slope. The first equation is a simple linear regression whilst the second one is a multipdual linear regression. Why we get higher R^2 can be because we put one more variable in equation 2 and that's why we get R^2 and that's an assumption you need to make.

- IV. We believe that is -0.718 is closer to the true elasticity because R^2 is greater in equation 2 and there is the -0.718 .
